AB A unique carotenogenic biosynthetic gene cluster was isolated from Pantoea agglomerans strain DC404, wherein the genetic organization of the cluster is crtE-idi-crtY-crtI-crtB-crtZ. The genes contained within this cluster encode geranylgeranyl pyrophosphate (GGPP) synthetase (CrtE), isopentenyl pyrophosphate isomerase (Idi), lycopene cyclase (CrtY), phytoene desaturase (CrtI), phytoene synthase (CrtB), and  $\beta$ -carotene hydroxylase (CrtZ). The gene cluster, genes and their

products are useful for the conversion of farnesyl pyrophosphate to carotenoids. Vectors containing those DNA segments, host cells containing the vectors, and methods for producing those enzymes by recombinant DNA technol. in transformed host organisms are disclosed.

AB The invention describes a method for the construction of gene clusters ("stacking of traits") in a recombination-capable host by introduction of foreign DNA using a transducing phage system is described. The method uses integrating cassettes that include a pair of flanking sites for site-specific recombination and a gene of interest with a selectable marker integrated into it by site-specific recombination and flanked by sites for site-specific recombination. The DNA is introduced into the host using a transducing phage. It then integrates into the host genome by homologous recombination using the flanking sequences. Integrants are then selected for using the selectable marker and the selectable marker is excised by site-specific excision from selected cells. After the first gene is introduced, a second and further genes can be introduced by further rounds of transduction, recombination, and selection. The method makes use of a nucleic acid integration cassette that has homol. to a specific site on a host chromosome for the insertion of genetic elements and the stacking of traits. Repetition of the method results in the stacking of traits on a single genetic element.

AB The invention relates to the use of promoter regions isolated from a <i>Methylobacter</i> sp. for gene expression and metabolic engineering in C1 metabolizing bacteria. Genes, ntrA, glnB, htpG, moxP and hps, have been identified in the <i>Methylobacter</i> genome that are responsive to various metabolic and growth conditions. The identified responsiveness				

of these genes allows for the use of their promoters in regulated gene expression in transgenic C1 metabolizing bacteria. In particular, the hps promoter, which in its native state drives the expression of 3-hexulose-6-phosphate synthase (HPS), was found to be useful for directing expression of heterologous coding regions (e.g., crtZ) in the obligate methanotroph *Methylobacter* sp. 16a.

AB Genes have been isolated from *Rhodococcus* and *Deinococcus* which encode a specific lycopene  $\beta$ -cyclase capable of converting acyclic carotenoids with at least one  $\psi$ -end group to the corresponding asym. carotenoid containing a single  $\beta$ -ionone ring end group. The genes are new. Transformed host cells expressing the present genes and methods for the bio-conversion of acyclic carotenoid substrates to corresponding asym. carotenoid are also provided. Thus the crtL gene from *Rhodococcus erythropolis* strain AN12 and *Deinococcus radiobacter* R1 which encodes a lycopene  $\beta$ -cyclase was isolated and characterized. Recombinant *Escherichia coli* strains already bearing the the crtEXIB operon were transformed with either a crtL or a crtY gene. Transformant containing the crtY gene produced  $\beta$ -carotene while those with the crtL gene produce  $\gamma$ -carotene.

AB A method for the production of carotenoid compds. is disclosed. The method  
relies on the use of microorganisms which metabolize single carbon  
substrates for the production of carotenoid compds. in high yields. Thus  
**Methylomonas** strain 16a was genetically enhanced to produce  
**beta.-carotene** and zeaxanthin from methane.
